### Trend Study 1-8-01

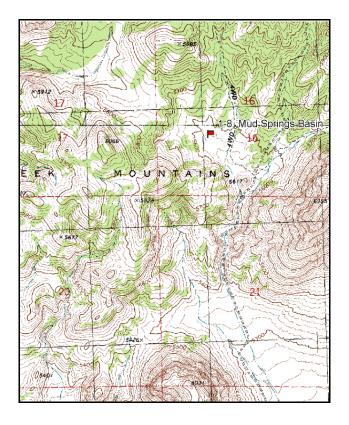

Study site name: <u>Mud Springs Basin</u>. Vegetation type: <u>Big Sagebrush-Grass</u>.

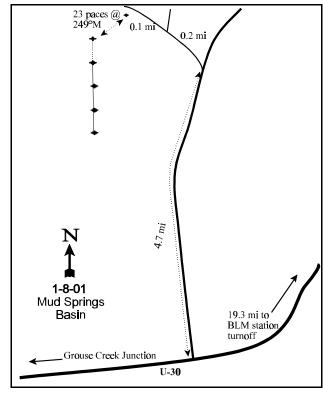

Compass bearing: frequency baseline 180 degrees magnetic.

Frequency belt placement: line 1 (11 & 95ft), line 2 (34ft), line 3 (71ft), line 4 (59ft).

#### LOCATION DESCRIPTION

On U-30 proceed 19 miles southwest from the Rosebud BLM station turn-off and turn right (north) onto a gravel road just before mile marker 14. Proceed 4.7 miles and take a fork to the left for 0.2 miles. Take a very faint road to the left for 0.1 miles to a witness post on the left side of the road. From the witness post, walk 17 paces on an azimuth of 182 degrees magnetic to the 0-foot stake of the frequency baseline marked by browse tag #7913. Bearing of the baseline is 180 degrees true.

#### DISCUSSION

#### Trend Study No. 1-8

The Mud Springs Basin trend study is located on critical deer winter range near the south end of the Grouse Creek Mountains, approximately 2 miles southwest of Mud Springs Basin. The site has an elevation of 5,600 feet and slight southwest aspect. The small basin in which the study is located contains numerous small ridges occupied by sparse fingers of juniper and black sagebrush separated by low areas (swales) occupied by the more deep rooted basin big sagebrush. The study samples a large sagebrush swale because of their obvious importance during winters with deeper snow like the winter of 1983-84. The pellet-group transect read in conjunction with the vegetative transect in 2001, estimated 29 deer days use/acre (73 deer days use/ha).

Soil is moderately deep and alluvially deposited with minimal surface rockiness. The soil has a loam texture and slightly alkaline reaction (7.8 pH). The amount of phosphorus could be a limiting factor as there is only 6.3 ppm where values less than 10 ppm have been shown to limit plant growth and development. Bare interspaces have pavement covering the surface, but the soil beneath is easily erodible. Ground cover is principally sagebrush crowns, native grasses, and cheatgrass. The ratio of bare soil to protective ground cover is fair and the erosion condition class was determined to be moderate in 2001. Most signs of erosion are from pedestalling, flow patterns, and abundant rills. The ample vegetation and litter cover combined with the lack of steep slope prevents more serious soil erosion problems. A number of small drainage channels traverse the area, however none are deep or highly active. Most appear relatively stable.

Browse composition consists mostly of Wyoming big sagebrush. Density was estimated at 5,866 in 1984. There was a considerable amount of rodent damaged plants encountered that year, yet percent decadency was still relatively low at 14%. The sagebrush stand appeared over-mature and decadent at first glance in 1984, but examination of the shrub density data suggested an age structure more typical of an expanding or regenerating population. The surviving mature and decadent plants received heavy deer use on those portions of the crown which protruded above the snow line yet vigor was not seriously depressed. Thus, the surviving plants looked ragged but nonetheless exhibited good vigor when examined in June of 1984. Population density declined 36% and percent decadency increased to 29% in 1990. Utilization was light and vigor was good on all but 50% of the decadent plants. Density continued to decline in 1996, while the number of mature plants increased from 1,400 plants/acre to 2,060. The lower density for sagebrush continues through 2001 where the population decreased from 3,240 to 2,540 plants/acre. The percentage of dead plants within the population has increased from 16% to 32%. Utilization, except for 1984, has mostly been light. Percent decadency has varied through the years, from a low of 14% in 1984 to a high of 29% in 1990. Percent decadence is currently 19%. Canopy cover of big sagebrush has gone from about 12% in 1996 to 14% in 2001.

Other shrubs, such as prickly phlox, narrowleaf low rabbitbrush, black sagebrush, and Nevada ephedra are distinctly secondary in importance. Density of narrowleaf rabbitbrush increased dramatically from 199 plants/acre to 3,300 since 1990. Some of the increase is due to the larger sample used in 1996 which better estimates shrub populations which have aggregated and/or discontinuous distributions. Currently ('01) it has shown a 42% decrease in it's population, probably the effects of prolonged drought.

Understory composition was dominated by a moderately dense stand of native perennial grasses in 1996, consisting of bluebunch wheatgrass, Indian ricegrass, Sandberg bluegrass, and bottlebrush squirreltail. These grasses produced nearly 15% cover in 1996. Currently ('01), they produce only about 11% cover. Cheatgrass brome, an annual, has increased in cover from 5% cover in the 1996, to 13% in 2001. Cheatgrass is becoming significantly more abundant. Forb diversity depends on timing and amounts of precipitation as species

numbers vary from each year it has been sampled. Species numbers have varied from a high of 29 species in 1996 to a low of only 9 species in 1990. Eighteen forb species were sampled in 2001. Nine species of annual forbs also occur on the site, combining to produce 22% of the herbaceous cover. Cheatgrass should be watched closely as it significantly increased in nested frequency and cover more than doubled since 1996.

#### 1984 APPARENT TREND ASSESSMENT

Long term trend seems relatively stable. Although the dominant browse species suffered heavy damage in 1983-84, regeneration and recovery should occur rapidly. In this deteriorated condition, high numbers of wildlife could cause further losses to the big sagebrush population. Soil is potentially highly erodible even though the current rate of soil loss is low.

#### 1990 TREND ASSESSMENT

Trend for soil is down due to a major increase in percent bare ground (13% to 30%). Litter cover also declined from 70% to 39%. Trend for big sagebrush is down. The number of mature plants declined from 3,066 to 1,400. Density of seedlings and young plants declined as well, but there appears to be sufficient numbers to maintain the population. Utilization of the sagebrush was light but percent decadency increased from 14% to 29%. Nearly half (44%) of the decadent plants appeared to be dying. The currently balanced age class structure, would indicate that the sagebrush population, heavily impacted by the harsh winters of the early 1980's is stabilizing. Trend for the herbaceous understory is up. All five perennial grasses increased in nested frequency and quadrat frequency values. For the forbs, a little over half had improved nested and quadrat frequency's.

TREND ASSESSMENT

soil - down (1) browse - down (1) herbaceous understory - up (5)

#### 1996 TREND ASSESSMENT

Trend for soil is up slightly. Percent bare ground declined from 30% to 13%, while litter and cryptogamic cover increased slightly. Trend for the key browse species, Wyoming sagebrush, is fairly stable since 1990. Density of mature plants increased while the number of seedling and young declined. Utilization was mostly light and percent decadence fell slightly from 29% to 25%. Vigor was good on all but 28% of the decadent sagebrush which were classified as dying. One cause for concern is the increase in density of narrowleaf low rabbitbrush which rose from 199 to 3,300 plants/acre. Due to the lack of seedlings and young during previous readings, some of the increase is likely due to the increased sample size used in 1996. Trend for the herbaceous understory is stable. Sum of nested frequency of grasses declined slightly while frequency of perennial forbs increased.

TREND ASSESSMENT

soil - up slightly (4) browse - stable (3) herbaceous understory - stable (3)

#### 2001 TREND ASSESSMENT

Trend for soil would be considered stable because the proportion of protective cover to bare soil has remained fairly stable. Trend for the key browse species, Wyoming sagebrush, is slightly down with continuing decreases in density, percent young have decreased from 12% down to only 3%. Percentage of decadent plants classified as dying have increased from 28% up to 67%, and percent dead within the population have also increased from 16% to 32%. Utilization was classified as mostly light. Those classified with poor vigor has increased from 7% to 13%. One cause of concern in 1996 was the increase in density of narrowleaf low rabbitbrush which rose from 199 plants/acre in 1990 to 3,300 plants/acre in 1996. Currently it has decreased by 42% to 1,900 plants/acre. Trend for the herbaceous understory is considered stable. However, even though the perennial grass component has remained stable, the forbs have decreased from making up 18% of the herbaceous cover down to only 7%. Cheatgrass has increased significantly in nested frequency, while its percent cover has more than doubled since the last reading.

#### TREND ASSESSMENT

soil - stable (3)

browse - slightly down (2)

<u>herbaceous understory</u> - stable overall (3)
